

Test Details	
Goal of Test	<p>The purpose of this test is to get the maximum throughput the ASA can process using HTTP traffic. This traffic model is more close to the real world traffic.</p> <p>In order to produce the TCP traffic the Spirent Avalanche 2900 was used ( 4, 2900's with 1 ten-gigabit interface each). When looking at the diagram the numbers 155, 156, 157, 158 are the individual 2900 chassis. To produce bi-directional traffic through the ASA one client port is placed on the outside pulling a 512K byte object from one server port on the inside, and one client port is placed on the inside pulling a 512K byte object form one server port on the outside. The Avalanche Tool is configured with 10672 clients and 16 servers. This comes down to 667 clients each pointing to one of the 16 servers. Each client walks an action list of 10 gets to the servers address. With HTTP 1.1 with persistence this results in 10 transactions per tcp connection. For each get the server responds with a 512K byte object. Below are screen shots of the test tool setup.</p>
Data to Record	<ol style="list-style-type: none"> <li>1. <i>show cpu</i></li> <li>2. <i>show conn count</i></li> <li>3. <i>show io-bridge</i></li> <li>4. Capture results from the test tool</li> </ol>
Estimated Time Needed	60 minutes

## Procedures

### DESCRIPTION

1. On the client side configure (Avalanche Clients):
  - a. 1500 SimUsers for the load on each avalanche 2900
  - b. 16 subnets, with 667 hosts (10.100 to 12.254) pointing to one server on the reflector and assign one to each port.
  - c. 10 GETs on the action profile
2. On the server side, configure:
  - a. One server per port
  - b. 512k Object size
3. Bidirectional traffic is used (Clients from the inside to the outside and vice-versa)
4. While traffic is at steady state take a screen shot of the live Client Stats.
