This article provides examples of SSL termination (front-end SSL; ACE acting as a server), SSL initiation (back-end SSL; ACE acting as a client), and end-to-end SSL configurations. For details about configuring SSL on the ACE, see the *Cisco Application Control Engine Module SSL Configuration Guide*.

To return to the main article, click here.

Contents

Example of an SSL Termination Configuration

The following example illustrates a running configuration of the ACE acting as an SSL proxy server; terminating SSL or TLS connections from a client and then establishing a TCP connection to an HTTP server. When the ACE terminates the SSL or TLS connection, it decrypts the cipher text from the client and transmits the data as clear text to the HTTP server. The SSL termination-specific configuration elements appear in bold in the example.

Example of an SSL Initiation Configuration

The following example illustrates a running configuration of the ACE acting as an SSL proxy client, initiating and maintaining an SSL connection between itself and an SSL server. The ACE receives clear text from an HTTP client, and then encrypts and transmits the data as cipher text to the SSL server. On the reverse side, the ACE decrypts the cipher text that it receives from the SSL server and sends the data to the client as clear text. The SSL initiation-specific configuration elements appear in bold in the example.

Examples of End-to-End SSL Configurations

This section provides two SSl end-to-end configuration examples. The first example combines the previous SSL termination example and the SSL initiation example. The second example is a simplified approach to end-to-end SSL that you can modify to suit your own needs.

Example of an End-to-End SSL Example that Combines the Termination and Initiation Examples

The following example illustrates an end-to-end SSL configuration, which combines front-end SSL and back-end SSL. The ACE receives encrypted text from an HTTP client, and also transmits the encrypted data as cipher text to the SSL server. On the reverse side, the ACE decrypts the cipher text that it receives from the SSL server and sends the data to the client as clear text. The SSL-specific configuration elements appear in bold in the example.
