

If you find that your presentation slides do not look as good as the originals, note the following:

1. Keep in mind that the internal conversion tool for Web Conferencing uses a machine configuration-dependent graphics context to render images for presentations. The number of colors available in the system's graphics context is a particularly important limiting factor. For example, if the video driver for a server running Web Conferencing is set up to display 256 colors, images produced on that server are limited to 256 colors and slides are of reduced display quality.
2. Make sure that all of your corporate fonts and standard Microsoft fonts, including Microsoft PowerPoint fonts, are loaded on to the web server.

Tip: The more complex the color and images, the slower the refresh. To improve refresh rates, try sharing and viewing without the background colors.
